

Using **expm** in packages

1 Introduction

The **expm** packages provides an R function **expm** to compute the matrix exponential of a real, square matrix. The matrix exponential of a matrix **A** is defined as

$$\begin{aligned} e^{\mathbf{A}} &= \mathbf{I} + \mathbf{A} + \frac{\mathbf{A}^2}{2!} + \dots \\ &= \sum_{k=0}^{\infty} \frac{\mathbf{A}^k}{k!}. \end{aligned}$$

The actual computations are done in C by a function of the same name that is callable by other packages. Therefore, package authors can use these functions and avoid duplication of efforts.

2 Description of the functions

The R function **expm** takes in argument a real, square matrix and returns its exponential. Dimension names are preserved:

```
> library(expm)
> m <- matrix(c(4, 1, 1, 2, 4, 1, 0, 1, 4), 3, 3)
> expm(m)

      [,1]      [,2]      [,3]
[1,] 147.8666 183.7651  71.79703
[2,] 127.7811 183.7651  91.88257
[3,] 127.7811 163.6796 111.96811

> dimnames(m) <- list(letters[1:3], LETTERS[1:3])
> m
```

```

      A B C
a 4 2 0
b 1 4 1
c 1 1 4

> expm(m)

      A      B      C
a 147.8666 183.7651  71.79703
b 127.7811 183.7651  91.88257
c 127.7811 163.6796 111.96811

```

The actual computational work is done in C by a routine defined as

```
void expm(double *x, int n, double *z)
```

where \mathbf{x} is the vector underlying the R matrix and \mathbf{n} is the number of lines (or columns) of the matrix. The matrix exponential is returned in \mathbf{z} . The routine uses the algorithm of Ward (1977) based on diagonal Padé table approximations in conjunction with three step preconditioning. The Padé approximation to $e^{\mathbf{A}}$ is

$$e^{\mathbf{A}} \approx R(\mathbf{A}),$$

with

$$R_{pq}(\mathbf{A}) = (D_{pq}(\mathbf{A}))^{-1} N_{pq}(\mathbf{A})$$

where

$$D_{pq}(\mathbf{A}) = \sum_{j=1}^p \frac{(p+q-j)!p!}{(p+q)!j!(p-j)!} \mathbf{A}^j$$

and

$$N_{pq}(\mathbf{A}) = \sum_{j=1}^q \frac{(p+q-j)!q!}{(p+q)!j!(q-j)!} \mathbf{A}^j.$$

See Moler and Van Loan (1978) for an exhaustive treatment of the subject.

The C routine is based on a translation made by Bates and Maechler (2007) of the implementation of the corresponding Octave function (Eaton, 2002).

3 Calling the functions from other packages

Package authors can use facilities from **expm** in two (possibly simultaneous) ways:

1. call the R level function **expm** in R code;

2. if matrix exponential calculations are needed in C, call the routine `expm`.

Using R level function `expm` in a package simply requires the following two import directives:

```
Imports: expm
```

in file DESCRIPTION and

```
import(expm)
```

in file NAMESPACE.

Accessing the C level routine further requires to prototype `expm` and to retrieve its pointer in the package initialization function `R_init_pkg`, where *pkg* is the name of the package:

```
void (*expm)(double *x, int n, double *z);

void R_init_pkg(DllInfo *dll)
{
    expm = (void (*) (double, int, double)) \
        R_GetCCallable("expm", "expm");
}
```

The definitive reference for these matters remains the *Writing R Extensions* manual.
